FAPESP GRANT #09/17675-5

WHAT?

- Use high-resolution LiDAR data to see how the calculated volume changes as resolution decreases.

WHY?

- Sedimentary Geology
- Numerical simulation of coastal systems
 - Volume is an important factor in simulations
 - Is SRTM good for this?

WHERE?

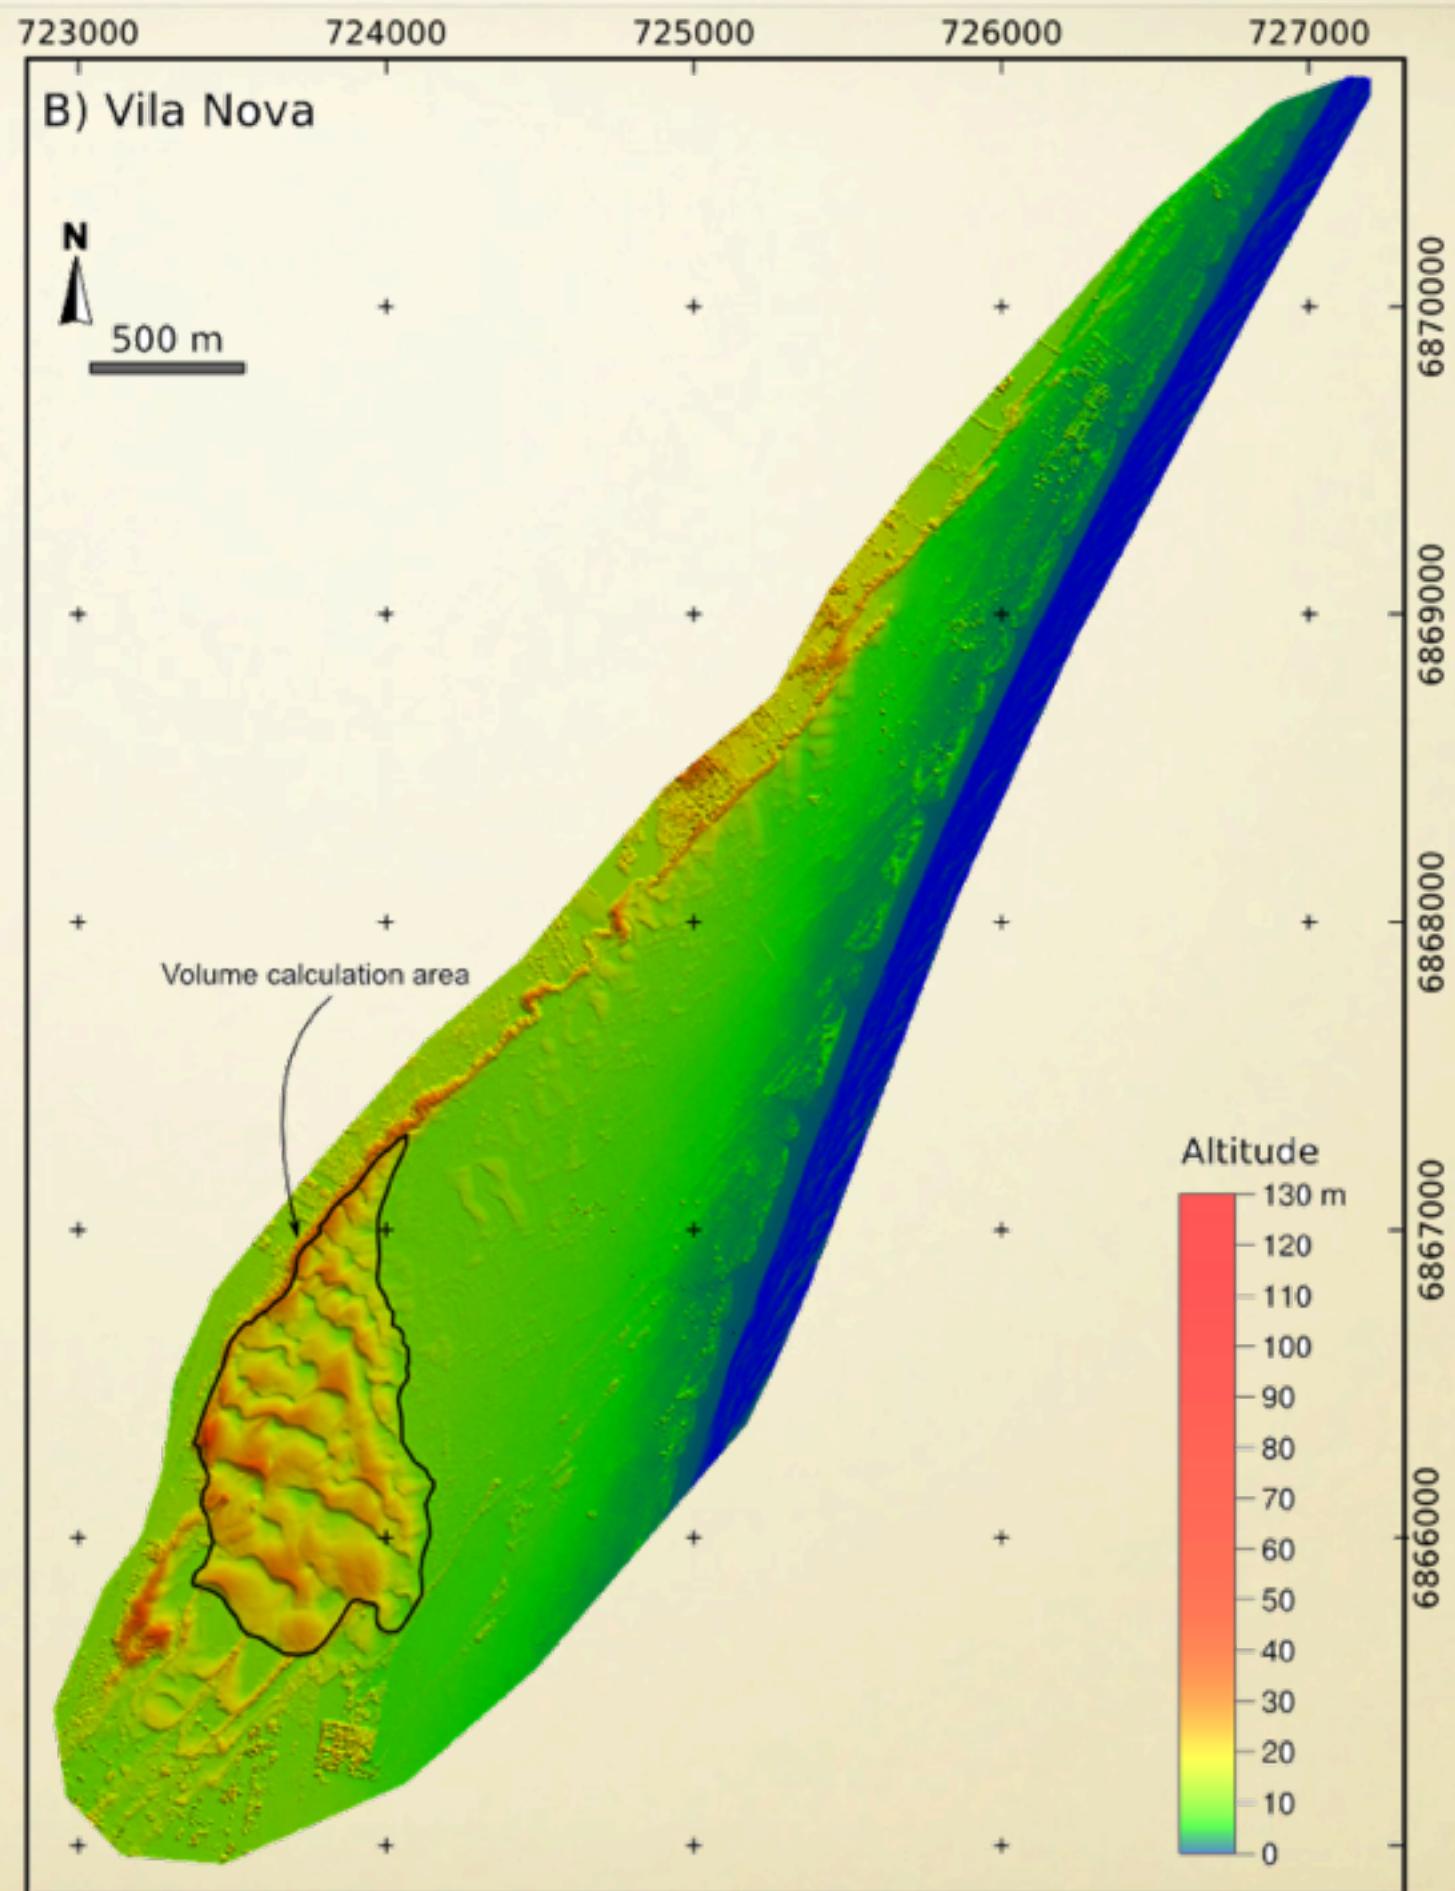

- Brazil (south)
- Garopaba and Imbituba, two small cities south of Florianópolis
 - Garopaba dune field
 - Vila Nova dune field

LIDAR SURVEY

- Geoid Laser Mapping Co.
- Optech ALTM 3100
- About one point per 0.5m
- Altitude of 1200 m (4000 ft).
- Vertical accuracy of 0.15m
- Processed with libLAS and GRASS

VOLUME CALCULATION

- Voxel-based (GRASS)
- Sea level (0m) as reference

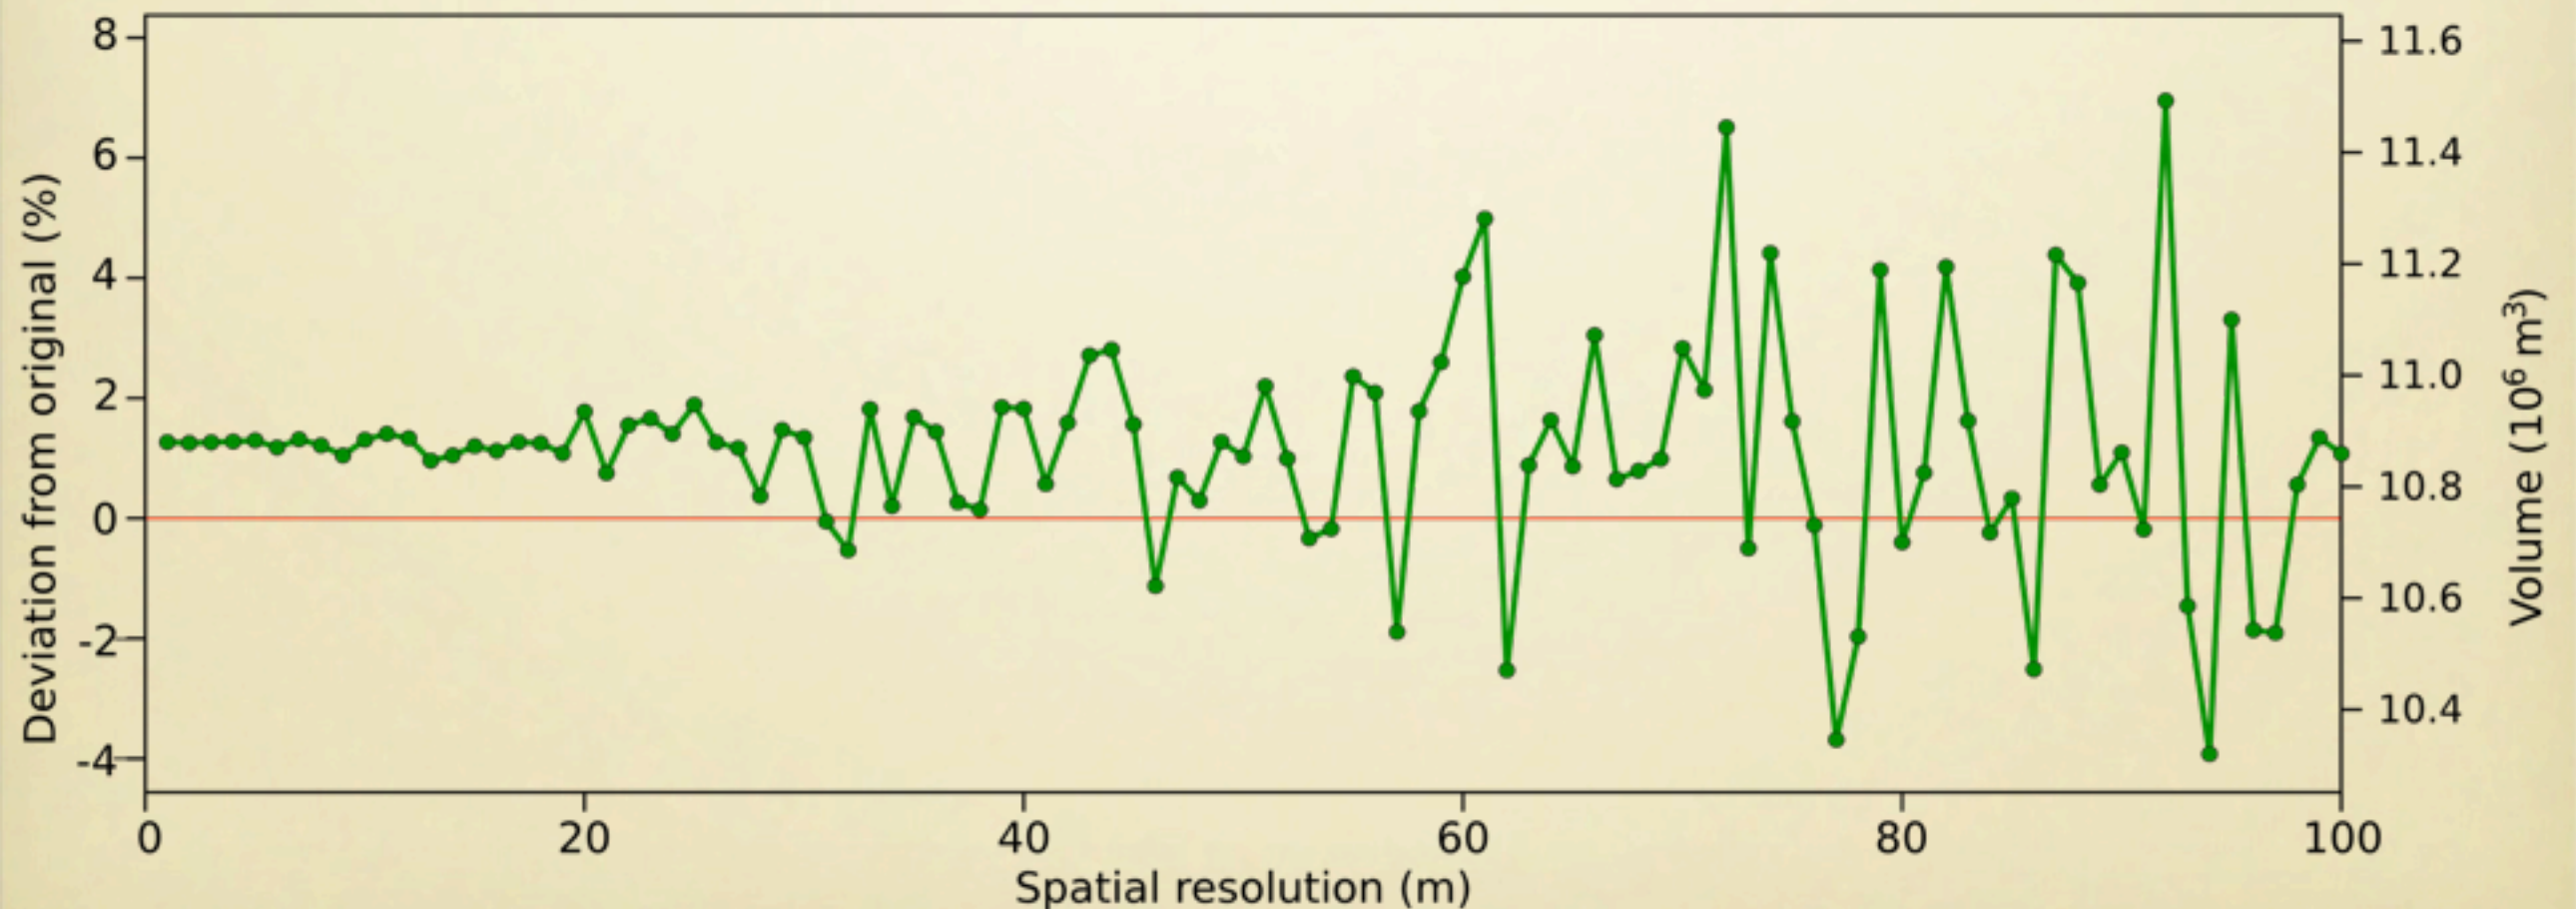

VOLUME CALCULATION

- ‘True’ volume
 - 0.5m resolution (horizontal and vertical)
- Resampled volume
 - 1m vertical resolution
 - 1-100m horizontal resolution
 - Elevation taken as the mean value of resampled cell

DEVIATION FROM 'TRUE'

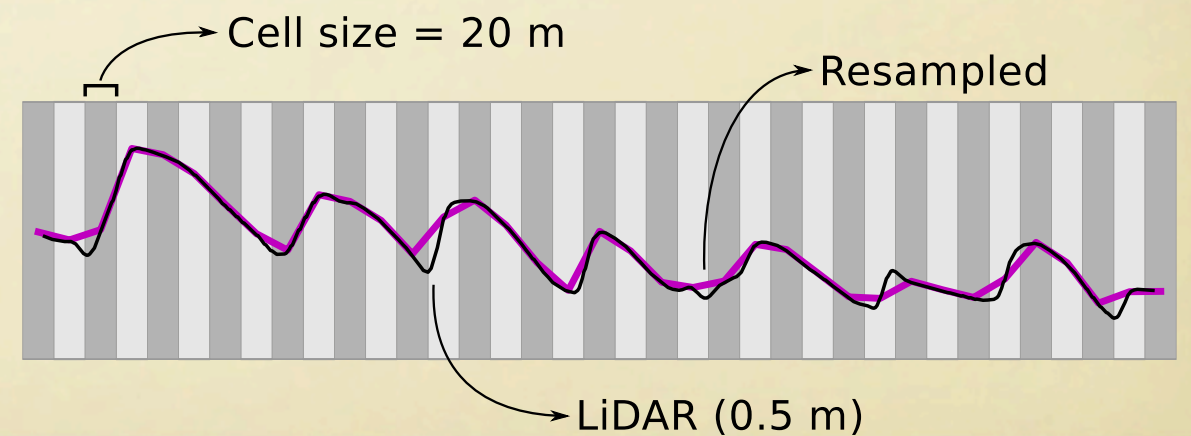

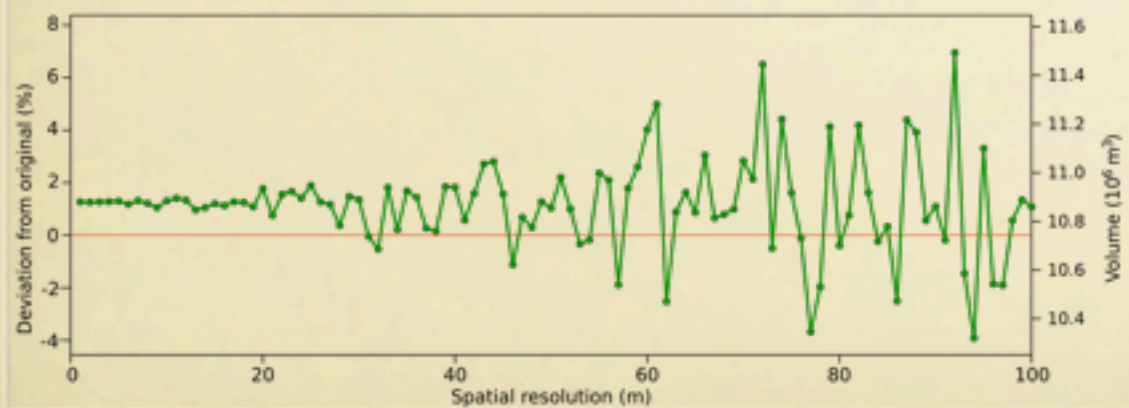

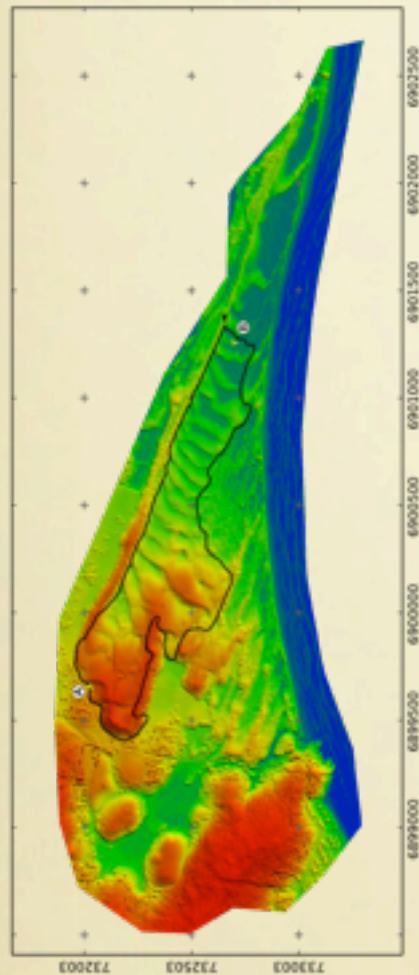

$$\text{Deviation} = \left(\frac{\text{Resampled volume} - \text{LiDAR volume}}{\text{LiDAR volume}} \right) \times 100$$

RMSE

VOLUME VARIATIONS

SRTM

Data	Dune field volume (m ³)	
	Garopaba	Vila Nova
LiDAR (0.5m)	10 605 783	16 045 793
SRTM (90 m)	10 076 400	17 236 800
Difference	-6.213 %	7.422 %

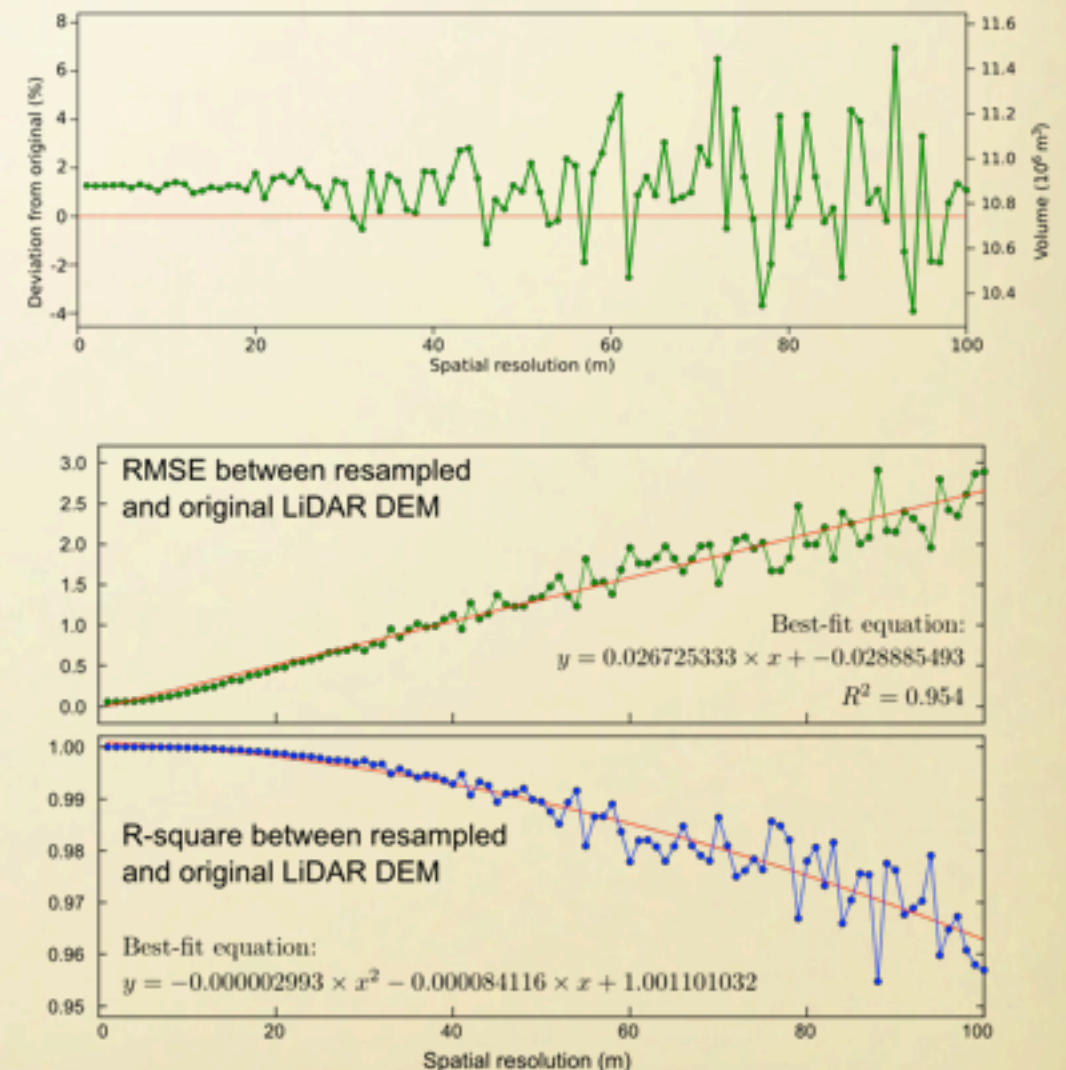

CONCLUSIONS (1)

- Fluctuation of volume values about the reference
 - random factor between
 - cell size
 - landform size
 - position of cell about landform

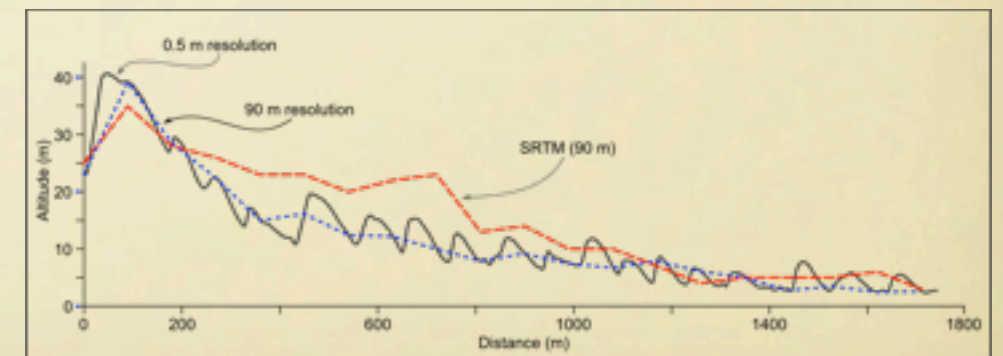

CONCLUSIONS (2)

- Optimal cell size?
 - 20m
 - increase in deviation + fluctuation
 - 30m
 - accuracy drops more rapidly

CONCLUSIONS (3)

- Deviation of SRTM from LiDAR
 - smaller than $\pm 10\%$
 - expected to decrease as area of field increases
- We consider SRTM to be a viable source of volume data for numeric simulations of dune field (and coastal systems) evolution

DON'T CLAP YET

GEOMORPHOMETRY 2013

- Bonito - Brazil
